

Scratchwork: Prime Number Theorem

Let's go straight for the Analytic Theorem.

Let $f(t)$ with $t \geq 0$ be a bounded and locally integrable function and suppose that the function

$$g(z) = \int_0^\infty f(t) e^{-zt} dt \text{ with } \operatorname{Re}(z) > 0$$

extends holomorphically to $\operatorname{Re}(z) \geq 0$. Then $\int_0^\infty f(t) dt$ and it equals $g(0)$.

On the one hand the language is standard, but the wording might be of some concern.

- $f : \mathbb{R} \rightarrow \mathbb{C}$ is defined only on the real axis \mathbb{R} and it is bounded $|f(t)| < M$ always.
- $g(z) = \int_0^\infty f(t) e^{-zt} dt$ is the **Laplace transform** extended to complex arguments $z \in \mathbb{C}$.
- “Locally integrable” is what we mean by “integrable” when we forget the domain of definition is \mathbb{R} or $\mathbb{R}_{\geq 0}$; Our example of a **locally integrable** function that is not **integrable** is:

$$f(x) = 1 \text{ for all } x \in \mathbb{R}$$

In fact, $\int_a^b f(x) = b - a$ however $\int_{\mathbb{R}} f(x) = \infty$. Another excellent example is:

$$f(x) = \begin{cases} \frac{1}{x} & x \neq 0 \\ 0 & x = 0 \end{cases}$$

This function is not locally integrable at $x = 0$, no neighborhood has of $x = 0$ has a integral $\int_{[-\epsilon, \epsilon]} f(x) \notin \mathbb{R}$ does not even converge to a number.

Could $\int_{[-\epsilon, \epsilon]} f(x)$ be something more exotic than a number? It is a **distribution** and in fact there is the **Cauchy Principal Value**.

- The theorem is designed with a specific choice of $f(t)$ in mind, it is:

$$f(t) = \theta(e^t) e^{-t} - 1 = \frac{1}{e^t} \left[\sum_{p \leq e^t} \log p \right] - 1$$

and then the Laplace transform is the zeta function (rather Dirichlet series) that we know stuff about:

$$g(z) = \frac{1}{z+1} \Phi(z+1) - \frac{1}{z} = \frac{1}{z+1} \sum_p \frac{\log p}{p^s} - \frac{1}{z}$$

so the question is whether we can extract information about $f(t)$ from $g(z)$:

$$\left[\sum_p \frac{\log p}{p^s} \right] \rightarrow \left[\sum_{p \leq x} \log p \right]$$

Hopefully that explains a bit what Zagier Theorem (or Newman's Theorem) was designed to do and why where was a need in the first place. There are these two measures of "size" and we'd like to explain why one is related to the other.

What could go wrong with the limit:

$$\left[g(z) = \int_0^\infty f(t) e^{-zt} dt \right] \xrightarrow{?} \left[g(0) = \int_0^\infty f(t) dt \right]$$

What goes wrong with plugging in $z = 0$? There was a great textbook called "Counterexamples in Analysis" and every sentence in this discussion requires about a dozen counterexamples. At least I need them, this counterfactual reasoning is very very difficult to me.¹ When I did analysis proofs, I would write a "wishful thinking" proof or a "bad" argument, and then gradually turn all the wrong steps into correct steps by accounting for all the exceptions that could occur.

Bad Proof #1 Laplace transforms are always very well-behaved.

$$g(z) = \int_0^\infty f(t) e^{-zt} dt \longrightarrow g(0) = \int_0^\infty f(t) dt$$

This is what we just said. By **continuity**, this limit should hold, for all $f : \mathbb{R} \rightarrow \mathbb{C}$.

CounterExample #1 $z = 0$ seems just slightly outside of the domain of $\{\operatorname{Re}(z) > 0\}$. How could it matter? Let's build a counterexamples: two functions: $g_1, g_2 : \Omega \subseteq \mathbb{C} \rightarrow \mathbb{C}$ such that:

- $g_1(z)$ and $g_2(z)$ are holomorphic on $\{\operatorname{Re}(z) > 0\}$
- $g_1(z) = g_2(z)$ agreeing on $\{\operatorname{Re}(z) > 0\}$
- $g_1(0) \neq g_2(0)$

Amazingly this counterexample does not exist. If two holomorphic functions agree on any open, however small, they are identical everywhere.

Example #2 The log function can be extended to complex numbers and has a definition as Laplace transform:

$$\Gamma(z+1) = \int_0^\infty e^{-w} w^z dw$$

This has a pole at $z = -1$ since $\log 0 = -\infty$. Then $\log 1 = 0$ but we have:

$$\log e^{i\theta} = i\theta \text{ for } \theta \in \mathbb{R} \text{ so that } \log 1 = 0, 2\pi i, 4\pi i, \text{ etc.}$$

Example #3 The zeta function is an infinite series, but it can also be analytic continued:

$$\begin{aligned} \zeta(z) &= \frac{1}{1^z} + \frac{1}{2^z} + \dots \\ \zeta(z) &= \frac{1}{\Gamma(z)} \int_0^\infty \frac{w^z}{e^w - 1} \frac{dw}{w} \end{aligned}$$

This formula is only true for $\operatorname{Re}(z) > 1$ for example:

$$\zeta\left(\frac{1}{2}\right) \neq 1 + \frac{1}{\sqrt{2}} + \frac{1}{\sqrt{3}} + \dots = \infty$$

It's very easy to take such a thing for granted we will take the series for $\zeta\left(\frac{1}{2}\right) \in \mathbb{R}$ and assign it a number.

¹Analysis would become my best subject because I knew I had to allocate the most time.

Special Case #3 Example #3 is important because of our choice of g :

$$\begin{aligned} g(z) &= \left. \frac{1}{z} \sum_p \frac{\log p}{p^z} - \frac{1}{z-1} \right|_{z=1} = \sum_p \frac{\log p}{p} - [\infty] \\ &\stackrel{pnt}{=} \int_0^\infty \left[\frac{1}{e^t} \sum_{p < e^t} \log p - 1 \right] dt \\ &= \int_0^\infty \left[\sum_{p < x} \log p - 1 \right] dx = \int_0^\infty f(t) dt \end{aligned}$$

A big part of PNT was to “regularize” a modest $[\infty] - [\infty]$ divergent infinite sum, and then relate it to an average over all $p < x$ as $x \rightarrow \infty$.

Example #2 If $z \in \mathbb{R}_{\geq 0}$ a real positive number, then freshman calculus integral holds like this:

$$\int_0^\infty e^{-zt} dt = \frac{1}{z}$$

This integral can be extended to all of $z \in \mathbb{C}$ or at least $z \in \{\operatorname{Re}(z) \geq 0\}$. Then

$$F(z) = \int_0^\infty e^{-zt} dt - \frac{1}{z} \stackrel{?}{=} 0$$

and this function is regular for $\operatorname{Re}(z) > 0$ and $F(z) = 0$ for all $z \in \mathbb{R}$. We can’t quite say “=” zero, but “equal, under appropriate condition” which could mean anything, really.

These analytic continuation discussions, trying to get formulas to take values outside of their original domain, lead to the concept of a **sheaf** of holomorphic functions. We get the notions like **Riemann surfaces** and **germs** and the branch cover or the **universal cover**.

Newmna’s proof is slightly oblique, and it’s not quantitative, but it’s short and it does lead to the Prime Number Theorem (with no rate of convergence). To me, the big challenge is relate information about the zeta function $\zeta(s)$ to information about the primes $\sum_{p < x} \log p$ and to continue we need to read past the “proof” sign.

Bad Proof #1a Clearly $g(z)$ is holomorphic. Let’s write out the Laplace transform:

$$g(z) = \int_0^\infty f(t) e^{-zt} dt$$

If $f(z)$ is bounded and holomorphic, then $g(z)$ is holomorphic. By continuity, $g(0) = \lim_{z \rightarrow 0} g(z)$.

$$\lim_{z \rightarrow 0} g(z) = \lim_{z \rightarrow 0} \int_0^\infty f(t) e^{-zt} dt = \int_0^\infty f(t) dt$$

The first equality is trivially true since $z \neq 0$ (or $\operatorname{Re}(z) \geq 0$) and the second integral is clearly true.²

Counterexample #2a Our counterexample is $\boxed{f(z) = 1}$ If $z \in \mathbb{R}_{\geq 0}$ a real positive number, then freshman calculus integral holds like this:

$$\int_0^\infty 1 e^{-zt} dt = \frac{1}{z}$$

²since it’s also holomorphic

This integral can be extended to all of $z \in \mathbb{C}$ or at least $z \in \{\operatorname{Re}(z) \geq 0\}$. Then

$$F(z) = \int_0^\infty 1 e^{-zt} dt - \frac{1}{z} \stackrel{?}{=} 0$$

and this function is regular for $\operatorname{Re}(z) > 0$ and $F(z) = 0$ for all $z \in \mathbb{R}$. I'm being slightly awful.

Bad Proof #2 If we integrate over a finite domain, that Laplace transform will be holomorphic as well:

$$g_T(z) = \int_0^T f(t) e^{-zt} dt$$

We could say "compact support" and integrate over all $t \geq 0$ and later it may be useful to write it out in this formal way.

If $f(t)$ is bounded and holomorphic, $g_T(z)$ is holomorphic as well. And finally:

$$\lim_{z \rightarrow 0} g_T(z) = g_T(0)$$

This is **Cauchy integral formula** or possibly Morera theorem. It remains to prove the exceedingly obvious:

$$\lim_{T \rightarrow \infty} g_T(0) = g(0)$$

It seems to be a modest change of limits. If $f(t)$ is holomorphic, i.e. $f(z + dz) = f(z) + f'(z) dz$ and bounded $|f(z)| < M$ then we could have:

$$\lim_{T \rightarrow \infty} \lim_{z \rightarrow 0} \int_0^T f(t) e^{-zt} dt = \lim_{z \rightarrow 0} \lim_{T \rightarrow \infty} \int_0^T f(t) e^{-zt} dt$$

and this is obviously true.

Bad Proof #3 The previous proof is problematic since we are trying to connect $g(0)$ to the limit of integrals

- near $z = 0$ we could $g(z) \rightarrow g(0)$
- near $z = 0$ we could say $\int_0^\infty f(t) e^{-zt} dt \rightarrow \int_0^\infty f(t) dt$
- away from $z \neq 0$ we could say $\int_0^\infty f(t) e^{-zt} dt = g(z)$

and we can't connect information away from $z = 0$ to information *near* $z = 0$. This is why we could use Cauchy integral formula:

$$g(0) = \frac{1}{2\pi i} \oint_C g(z) \frac{dz}{z}$$

where $C = 0 + \epsilon S^1 = \{\epsilon e^{2\pi i \theta} : 0 < \theta < 2\pi\}$ and we'll let $\epsilon = T$ and $T \rightarrow \infty$ and we could be done.

(to be continued ...)

We can recover $g(0)$ from nearby points in a number of ways: this is the magic property of holomorphic functions. This is why we celebrate when we find them:

$$g(0) = \frac{1}{2\pi i} \oint_C g(z) e^{zT} \left(1 + \frac{z^2}{R^2}\right) \frac{dz}{z}$$

The right hand side has three inputs:

- $C = \{z = R e^{2\pi i \theta} : 0 < \theta < 2\pi\}$ a circle centered at $z_0 = 0$
- The radius of the circle $R \rightarrow \infty$ which turn into a mollifier $1 + (z/R)^2$.
This is necessary since I lied about the contour it's really:

$$C' = \partial\left(\{|z| < 1\} \cap \{\operatorname{Re}(z) > -\delta\}\right)$$

but Zagier is making it too complicated let's just let $C = R S^1$ be a circle.

- The limit of the (finite) Laplace transform T which is also tending to infinity, $T \rightarrow \infty$.

So I am going to improve on Zagier's approach a little bit and take out that ridiculous factor:

$$\begin{aligned} g(0) &= \frac{1}{2\pi i} \oint_C g(z) e^{zT} \frac{dz}{z} \\ &= \frac{1}{2\pi i} \oint_C \left[\int_0^\infty f(t) e^{-zt} dt \right] e^{zT} \frac{dz}{z} \end{aligned}$$

and I have set $T = \infty$ because Zagier is being completely ridiculous. This is just the Laplace transform, but now the ray is pointing in different directions. We are integrating over the lines $e^{i\theta}\mathbb{R} \subset \mathbb{C}$ and taking the average.

Trivial New Lemma $g(z)$ is the Borel transform of the partial sums $\sum \log p$. (I could try to publish this.)

Proof: Borel summation is a way to add together badly divergent series, such as $\sum n! = 1 + 2! + 3! + \dots$. However we need authoritative source; we use Sauzin [3]. Borel summation has been around since 1900, but now it's less controversial.³ GH Hardy discusses both the Prime Number Theorem, Euler-Maclaurin Summation and the Borel transform in his textbook **Divergent Series**, which was published after he died.

³Especially after seeing the horrifying divergences in Quantum Field Theory, these seem rather tame.

Sauzin's Version part of why I know there should be a divergent series approach to PNT stems from a footnote in Sauzin's paper and alternatively it was in Hardy's book "Divergent Series" but neither of them fill in the details. In this note (if I ever clean it up) we try to explain what is being "regularized".

He defines the Laplace transform (at angle $\theta = 0$) by an integral from $[0, +\infty)$, where the direction of infinity matters a lot now:

$$(\mathcal{L}^0 \phi)(z) = \int_0^{+\infty} e^{-z\zeta} \phi(\zeta) d\zeta$$

He assumes $\phi : \mathbb{R}^+ \rightarrow \mathbb{C}$ is continuous, we just assume locally integrable (i.e. that the integration $\int_a^b \phi(t) dt \in \mathbb{R}$ will in fact return a number), and a condition:

$$|\phi(t)| \leq A e^{ct} \text{ we settle for } |\phi(t)| \leq A$$

and the integral "makes sense" for the complex half plane:

$$\Pi_0 := \{z \in \mathbb{C} : \operatorname{Re}(z) > 0\}$$

We know that $\mathcal{L}^0 \phi$ is holomorphic on Π_0 but not on the slightly larger area:

$$\Pi'_0 := \{z \in \mathbb{C} : \operatorname{Re}(z) \geq 0\}$$

Lemma # 1 We can take a Laplace transform:

$$\begin{aligned} \mathcal{L}^0(\zeta^n/n!)(z) &= z^{-(n+1)} \\ \mathcal{L}^0(\zeta^{\nu-1}/\Gamma(\nu))(z) &= z^{-\nu} \end{aligned}$$

$$\int_0^{+\infty} e^{-s} s^n ds = n!$$

The last one is the only one I ever use, but the middle one points an extension.

Lemma #2

$$\begin{aligned} \mathcal{L}^0(-t\phi) &= d\phi/dz \\ \mathcal{L}^0(e^{-ct}\phi) &= \phi(z+c) \\ \mathcal{L}^0(1 * \phi) &= z^{-1}\phi(z) \\ \mathcal{L}^0(d\phi/dt) &= z(\mathcal{L}^0\phi)(z) - \phi(0) \end{aligned}$$

What that, Sauzin phrases the Zagier-Newman lemma quite nicely:

$$\lim_{T \rightarrow \infty} \int_0^T \phi(t) dt = (\mathcal{L}^0 \phi)(0)$$

Despite having a general formula that works for all $\operatorname{Re}(z) > 0$ there was not guarantee it worked for $z = 0$. Then you are referred to his paper so we never get a statement of what is being regularized, or whether 1-summation techniques are actually used.

Zagier uses:

$$g(0) = \frac{1}{2\pi i} \oint g(z) \frac{dz}{z} = \frac{1}{2\pi i} \oint \left[\int_0^\infty e^{-zt} f(t) dt \right] \frac{dz}{z} = \frac{1}{2\pi i} \int_0^{2\pi} \int_0^\infty e^{-Rte^{i\theta}} f(t) dt d\theta$$

Sauzin makes a distinction between a function, the power series that can represent it and it's asymptotic expansion:

- $\hat{\phi} : \mathbb{R}^+ \rightarrow \mathcal{C}$ (the original function)
- $\phi := \mathcal{L}^0 \hat{\phi}$ (the Laplace transform)
- $\tilde{\phi}(z) := \mathcal{B}^{-1} \hat{\phi}$

The Borel transform is just defined as an algebraic rule:

$$\mathcal{B} : \tilde{\varphi} = \sum_{n=0}^{\infty} a_n z^{-(n+1)} \rightarrow \hat{\varphi} = \sum_{n=0}^{\infty} a_n \frac{\zeta^n}{n!}$$

(his use of the letter ζ is not convenient for us). $\mathcal{B} : z^{-1}\mathbb{C}[[z^{-1}]] \rightarrow \mathbb{C}[[\zeta]]$ is just an algebraic rule changing one formula (an infinite power series) into another. These things don't have to be "holomorphic" or have any other nice behavior. Later Sauzin will prove that \mathcal{B} and \mathcal{L}^θ should behave nicely to each other:

$$\mathcal{L}^0 \hat{\varphi}(z) \sim_1 \mathcal{B}^{-1} \hat{\varphi}(z) \text{ uniformly for } z \in \Pi_0 = \{\operatorname{Re}(z) > 0\}$$

This is called a "1-Gevrey asymptotic expansion" and the operator $\mathcal{L}^0 \circ \mathcal{B}$ is called **Borel-Laplace summation**.

Prime Number Theorem We wish to regularize the sum:

$$\int_0^\infty \left[\frac{1}{x} \sum_{p < x} \log p \right] dx \sim_1 \sum_p \frac{\log p}{p}$$

Resurgence lets us formula subtract off the infinite parts $\mathcal{L}^0(1) = 1/z$ (or we guess ahead of time), and the prime number theorem falls out of this.

$$\int_0^\infty e^{-st} \left[\frac{1}{x} \sum_{p < x} \log p \right] dx \sim_1 \frac{1}{s} \sum_p \frac{\log p}{p^s}$$

and we expand around $s = 1 + \epsilon e^{i\theta}$ (possibly with $\epsilon \rightarrow \infty$, which makes absolutely no sense at all). □

Remark: $\sum \frac{\log p}{p^s} - \frac{1}{s}$ is holomorphic for $\operatorname{Re}(s) \geq 1$ no extra poles, except $s = 1$ (which we subtracted out). This is where we used $\zeta(1 + it) \neq 0$ and showed that $g(z)$ is holomorphic for $\operatorname{Re}(z) \geq 1$ (not just $\operatorname{Re}(z) > 1$)

NOTE: a few things need to happen here:

- I'm not too obsessed with Riemann hypothesis but maybe valuable to extend just over the $\operatorname{Re}(s) = 1$ line. The zero-free region is much bigger than that, almost to $\operatorname{Re}(s) = \frac{1}{2}$. A lot of these proofs about extracting the last possible bit of accuracy from an estimate do not interest me very much as I can't even understand the most basic estimates and have struggled this much on PNT with no error term.
- There are a few other "Tauberian" proofs (longer and more complicated) which could be turned into statements about divergent series. These could also be considered ways of extending regularization methods. Likely, these are superseded by judicious standard techniques in **functional analysis**.
- Why do all of this? Show examples from L-functions of number fields or automorphic forms.
- math.NT routinely publishes "analytic" proofs but not *a priori* PNT. Could be **Cebotarev Density Theorem**. These days I'm also liking Journal of Number Theory.
